Optimal Product Designs for Multivariate Regression with Missing Terms

HOLGER DETTE and INGO RÖDER

Technische Universität Dresden

ABSTRACT. A multivariate polynomial regression on the $q$-cube is considered where not all products of the explanatory variables are present in the model. Using an approach of Lim & Studden (1988) D-optimal product designs for a large class of models of this type are determined in terms of their canonical moments and the efficiencies of these designs are investigated. It is demonstrated that the D-optimal product design provides an efficient solution of an optimal design problem, which is for nearly all cases unsolved.

Key words: D-optimality criterion, multivariate polynomial regression, missing interactions, product designs

1. Introduction

Consider a multiple regression of degree $m$ in $q \geq 1$ variables

$$Y(x) = \alpha_0 + \sum_{i=1}^{q} \alpha_i x_i + \sum_{1 \leq i_1 < i_2 \leq q} \alpha_{i_1 i_2} x_{i_1} x_{i_2} + \cdots + \sum_{1 \leq i_1 \leq \cdots \leq \text{l}_m \leq q} \alpha_{i_1 \ldots \text{l}_m} \prod_{j=1}^{\text{l}_m} x_{i_j}$$

(1)

where the controlled variable $x = (x_1, \ldots, x_q)^T$ is chosen from the compact design space $[-1, 1]^q$. The regression functions are the $\binom{m+q}{q}$ multiple monomials up to degree $m$

$$\prod_{j=1}^{q} x_{i_j}^{h_j} \quad \text{with} \quad \sum_{j=1}^{q} h_j \leq m.$$  

(2)

An approximate design is a probability measure on the $q$-cube $[-1, 1]^q$ with finite support $x_1, \ldots, x_q$ and masses $\xi_1, \ldots, \xi_q$. The weight $\xi_j$ gives the relative proportion of the total observations taken at the point $x_j$ ($j = 1, \ldots, l$). While properties of designs for the multivariate polynomial regression (1) and product type multivariate models have been studied intensively in the literature (see e.g. Kono, 1962; Farrel et al., 1967; Lim & Studden, 1988; Rafajłowicz & Myszka, 1988, 1992; Wong, 1994), optimal designs for “incomplete” multivariate models have not been studied so far. This paper considers the problem of designing an experiment for a multivariate polynomial regression (1) where not necessarily all $\binom{m+q}{q}$ monomials of the form (2) appear in the model. To be more precise let for $h_1, \ldots, h_q \in \{0, \ldots, m\}$ with $\sum_{j=1}^{q} h_j \leq m$

$$\mathcal{I}_{h_1, \ldots, h_q} = \begin{cases} 1 & \text{if } \prod_{j=1}^{q} x_{i_j}^{h_j} \text{ appears in the multivariate polynomial regression} \\ 0 & \text{else} \end{cases}$$

denote $\binom{m+q}{q}$ given numbers with values 0 or 1 and define a linear model by

$$Y(x) = \sum_{h_1, \ldots, h_q \in \{0, \ldots, m\}} \mathcal{I}_{h_1, \ldots, h_q} \left( \alpha_{h_1 \ldots h_q} \prod_{j=1}^{q} x_{i_j}^{h_j} \right).$$

(3)
The multivariate polynomial regression (3) has
\[
N_{q,m,x} = \sum_{h_1,\ldots,h_q \in [0,\ldots,m]} \mathcal{J}_{h_1,\ldots,h_q}
\]
parameters and the indicator functions \(\mathcal{J}_{h_1,\ldots,h_q}\) specify the monomials defined by (2) which appear in the “incomplete” model (3). As a simple example consider the case \(q = 3\), \(m = 2\) and the polynomial
\[
\alpha_0 + \alpha_1 x_1 + \alpha_2 x_2 + \alpha_3 x_3 + \alpha_4 x_1 x_2 + \alpha_5 x_1^2
\]
which emerges from (3) by the special choice
\[
\mathcal{J}_{0,0,0} = \mathcal{J}_{1,0,0} = \mathcal{J}_{0,1,0} = \mathcal{J}_{0,0,1} = \mathcal{J}_{1,1,0} = \mathcal{J}_{2,0,0} = 1,
\]
\[
\mathcal{J}_{1,0,1} = \mathcal{J}_{0,1,1} = \mathcal{J}_{0,2,0} = \mathcal{J}_{0,0,2} = 0.
\]
The vector of regression functions \(f(x)\) in the model (3) consists of the \(N_{q,m,x}\) monomials \(\prod_{j=1}^q x_j^{h_j}\) satisfying \(\sum_{j=1}^q h_j \leq m\) and \(\mathcal{J}_{h_1,\ldots,h_q} = 1\). For a given design \(\xi\) on the \(q\)-cube \([-1,1]^q\) the information matrix is defined by
\[
M(\xi) = \int_{[-1,1]^q} f(x)f(x)^T \, d\xi(x).
\]
By statistical considerations a good design maximizes an appropriate (concave) function of the information matrix. A design is called D-optimal if \(\xi\) maximizes the determinant of the information matrix \(M(\xi)\). D-optimal designs for the “complete” polynomial regression (1) (or equivalently for model (3) with \(\mathcal{J}_{h_1,\ldots,h_q} = 1\) for all \(h_1,\ldots,h_q\)) have been determined numerically by Farell et al. (1967) \((m = 3, q = 2)\) and Lim & Studden (1988) \((m = 3, 4, 5, q = 2; m = q = 3)\). For larger values of \(m, q\) the numerical difficulties increase rapidly and the last named authors proposed optimal product designs in order to produce at least efficient designs for the “complete” model (1). In this paper we will determine D- and \(D_\Sigma\)-optimal product designs for many of the “incomplete” models defined in (3). Our main tool is the theory of canonical moments (see Studden, 1980, 1982a, b) which allows an explicit description of the D-optimal product design by the canonical moments of its factors. Some tools for the calculation of the support points and weights of a design from its canonical moments are given in the Appendix in order to make the paper self-contained. Special examples are presented in section 3 while section 4 investigates the multivariate polynomial regression (1) where some of the “highest” terms \(x_j^m\) are not present in the model. Efficiency calculations indicate that the observations of Lim & Studden (1988) with respect to the excellent efficiencies of optimal product designs in the “complete” model carry over to the “incomplete” models of the form (3). The results of this paper have been implemented in the program OPTIMAL under MS-DOS which allows an efficient calculation of D-optimal product designs for the model (3) and is available from the authors. For a more detailed description of the program see Röder (1994).

2. D- and \(D_\Sigma\)-optimal product designs for “incomplete” models

Let \(\eta = \xi_1 \times \cdots \times \xi_q\) denote a product design on the \(q\)-cube \([-1,1]^q\) (which means that \(\xi_j\) is a probability measure on the interval \([-1,1], j = 1,\ldots,q\)) and define \(\Xi_q\) as the set of all product designs on \([-1,1]^q\). A D-optimal product design for the “incomplete” polynomial regression (3) is a solution of the problem
\[
\text{maximize } \det(M(\eta)) \text{ with respect to } \eta \in \Xi_q.
\]
A standard argument in design theory shows that the D-optimal product design \( \eta^* = \xi^*_1 \times \cdots \times \xi^*_q \) has symmetric components \( \xi^*_j \) and we can restrict ourselves to designs of this type which we call symmetric product designs.

In what follows we denote by \( W_{i(j)}(x_j) \) \((i = 0, \ldots, m)\) the monic orthogonal polynomial of degree \( i \) with respect to the symmetric measure \( \xi_j \) defined by

\[
\int_{-1}^{1} W_{k(j)}(x_j)W_{i(j)}(x_j) \; d\xi_j(x_j) = 0 \quad \text{for } l \neq k
\]

(here \( \xi_j \) is the \( j \)th factor of the product design \( \eta = \xi_1 \times \cdots \times \xi_q \)). The polynomials \( W_{i(j)}(x_j) \) can be defined recursively in terms of the canonical moments of the measure \( \xi_j \) (see Lim & Studden, 1988). To this end let \( \xi \) denote a probability measure on the interval \([-1, 1]\) with moments \( c_i = \int_{-1}^{1} x^i \; d\mu(x) \). Let \( c_i^+ \) denote the maximum of the \( i \)th moments \( \int_{-1}^{1} x^i \; d\mu(x) \) over the set of all probability measures having given moments \( c_1, \ldots, c_{i-1} \) and let \( c_i^- \) denote the corresponding minimum. The \( i \)th canonical moment is defined as

\[
p_i = \frac{c_i - c_i^-}{c_i^+ - c_i^-} \quad i = 1, 2, \ldots
\]

whenever \( c_i^- < c_i^+ \) and undefined if \( c_i^- = c_i^+ \). Note that the canonical moments vary in the interval \([0, 1]\) because \( c_i^- \leq c_i \leq c_i^+ \). A design \( \xi \) is symmetric if and only if the canonical moments of odd order satisfy \( p_{2i-1} = 1/2 \) whenever they are defined (see Lau & Studden, 1985). For more details we refer the reader to the work of Studden (1980, 1982a, b). If \( p_i \) denotes the \( i \)th canonical moment of the symmetric factor \( \xi_j \), then the monic orthogonal polynomials with respect to the measure \( d\xi_j(x) \) satisfy the recursion (\( q_i^0 = 1 \))

\[
W_{i+1(j)}(x_j) = x_jW_{i(j)}(x_j) - q_i^{(i)} W_{i-1(j)}(x_j) \quad i \geq 0
\]

with initial conditions \( W_{-1(j)}(x_j) = 0, W_{0(j)}(x_j) = 1 \) (see Lim & Studden, 1988). Note that \( q_i^{(i)} \) is defined by \( q_i^{(i)} := 1 - p_i \).

Let \( f(x) \) denote the vector of regression functions in the model (3). We define a corresponding vector \( g_\eta(x) \) of products of monic orthogonal polynomials as follows. If the \( l \)th component of \( f(x) \) is \( \Pi_{h \in s} x_{h}^{j_h} (h_1, \ldots, h_q \in \{0, \ldots, m\}, \sum_{h \in s} j_h \leq m, s \subset \{1, \ldots, q\} = 1) \) then the \( l \)th component of \( g_\eta \) is defined as \( \Pi_{h \in s} W_{h(j)}(x_j) \) (note that \( g_\eta \) depends on \( \eta = \xi_1 \times \cdots \times \xi_q \)). In order to determine optimal product designs in the “incomplete” model (3) explicitly we need the following basic assumption.

**Assumption 2.1**

There exists a symmetric product design \( \eta \) with non-singular information matrix (6) and there exists a permutation matrix \( Q \) such that

\[
Qg_\eta(x) = A_\eta Qf(x)
\]

where \( A_\eta \) is a lower triangular matrix with determinant 1.

A necessary and sufficient condition for assumption 2.1 is that, if \( s_1, \ldots, s_q = 1 \), then \( s_{h_1, \ldots, h_q} = 1 \) for every set \( (h'_1, \ldots, h'_q) \) such that \( h'_j \leq h_j \) and \( h_j \) and \( h'_j \) have the same parity for \( j = 1, \ldots, q \). It also follows readily from the recursive relation (9) that the existence of a symmetric product measure \( \eta^* \) (with non-singular information matrix) and a permutation matrix \( Q \) satisfying (10) implies that (10) is satisfied for all symmetric product designs \( \eta \in \Xi_q \) with \( \det M(\eta) > 0 \) (with the same matrix \( Q \)). As an example consider the model (4) and define \( f(x) = (1, x_1, x_2, x_3, x_1 x_2, x_1^2) \) then, by the recursion (9), \( g_\eta(x) = \ldots \)
\((1, x_1, x_2, x_3, x_1, x_2, x_1^2 - p_2^{(1)})^T (\eta = \xi_1 \times \xi_2 \times \xi_3)\) and a suitable choice for \(Q\) is \(Q = I_6\) and

\[
A_\eta = \begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 \\
-p_2^{(1)} & 0 & 0 & 0 & 0 & 1
\end{bmatrix}
\]

Further illustrations for assumption 2.1 are given in the following section. Throughout this paper we define

\[m_j := \max \left\{ h_j \mid J_{h_1, \ldots, h_q} = 1 \right\} \tag{11}\]

as the largest exponent of the variable \(x_j\) in the incomplete regression (3) \((j = 1, \ldots, q)\) and

\[J(i, j, k) := \sum_{x_j^{(k)}: h_j \leq k} J_{h_1, \ldots, h_q} \tag{12}\]

as the number of terms in the model (3) which are of degree smaller than or equal to \(k\) and which contain the factor \(x_j^i\) \((i = 1, \ldots, k, j = 1, \ldots, q)\).

**Theorem 2.1**

The D-optimal product design for an “incomplete” polynomial regression (3) satisfying assumption 2.1 is given by \(\eta = \xi_1^* \times \cdots \times \xi_q^*\). Here, for \(j = 1, \ldots, q, \xi_j^*\) is a probability measure on the interval \([-1, 1]\) which is uniquely determined by its canonical moments

\[
p_{i,j}^{(2l-1)} = \frac{1}{2}, \quad l = 1, \ldots, m_j,
\]

\[
p_{i,j}^{(2l)} = \frac{\sum_{i=1}^{m} J(i, j, m)}{\sum_{i=1}^{m} J(i, j, m) + \sum_{i=l+1}^{m} J(i, j, m)}, \quad l = 1, \ldots, m_j - 1,
\]

\[p_{i,j}^{(2m_j)} = 1,
\]

where \(m_j\) and \(J(i, j, m)\) are defined in (11) and (12).

**Proof.** The discussion following (7) shows that the optimal product design must be symmetric which implies for the canonical moments of its factors \(p_{i,j}^{(2l-1)} = 1/2\) whenever these are defined. By assumption 2.1 we obtain for the information matrix (6) of a symmetric product design \(\eta = \xi_1^* \times \cdots \times \xi_q^*\)

\[
M(\eta) = \int_{[-1,1]^d} Q^T A_\eta^{-1} Q g_\eta(x) g_\eta^T(x) Q^T (A_\eta^T)^{-1} Q d\eta(x)
\]

and the determinant of this matrix is given by

\[
\det(M(\eta)) = \det \left( \int_{[-1,1]^d} g_\eta(x) g_\eta^T(x) d\eta(x) \right)
\]

\[
= \prod_{i=1}^{q} \left( \int_{-1}^{1} \left( \int_{-1}^{1} W_{i,j}(x) \, d\xi_j(x) \right) \right)^{J_{i,j}}
\]

\[
= \prod_{j=1}^{q} \prod_{i=1}^{m_j} \left( \int_{-1}^{1} \left( \int_{-1}^{1} W_{i,j}^2(x) \, d\xi_j(x) \right) \right)^{J(i,j,m)} \tag{14}
\]

with

$$J(i, j, m) = \sum_{h_1, \ldots, h_q} \mathcal{J}_{h_1, \ldots, h_q} (i = 1, \ldots, m, j = 1, \ldots, q).$$

The second line in (14) follows from the first by using the orthogonality relation (8) of the polynomials $W_{i(j)}(x_i)$ which implies that the matrix

$$\int_{[-1, 1]^d} g_x(x)g_x^T(x) \, d\eta(x)$$

is diagonal with elements given by the integrals of the squares of the coefficients of $g_x(x)$. The maximization of det $(M(\eta))$ with respect to the product design $\eta = \xi_1 \times \cdots \times \xi_q$ can now be carried out as a maximization of the factors

$$A_j(\xi_j) = \prod_{i=1}^m \left[ \int_{-1}^1 W_{i(j)}(x_i) \, d\xi_j(x_i) \right]^{J(i, j, m)}$$

with respect to the (univariate) measure $\xi_j$. By lem. 4.3 in Lim & Studden (1988) we obtain

$$A_j(\xi_j) = \prod_{i=1}^m \left[ 2^{2i} \prod_{l=1}^i q^l_{2l-2} p^l_{2l-1} q^l_{2l-1} p^l_{2l-1} \right]^{J(i, j, m)} = \prod_{l=1}^m \left[ q^l_{2l-2} p^l_{2l-1} \right]^{J(i, j, m)}$$

where $p^l_{2l}$ denotes the $i$th canonical moment of $\xi_j$ and $q^l_{2l-1} = 1/2$ (by symmetry of $\xi_j$). A maximization of $A_j(\xi_j)$ in terms of the even canonical moments $p^l_{2l}$ yields (13). Note that

$$\sum_{i=1}^m J(i, j, m) = 0$$

whenever

$$l > m_j = \max \{ h_j \mid J_{h_1, \ldots, h_q} = 1 \}.$$

The uniqueness of the D-optimal product design follows, because $p^l_{2l} = 1$ implies the uniqueness of the single factor $\xi_j$.

Theorem 2.1 provides a complete solution of the D-optimal design problem in the class of product designs for all “incomplete” models satisfying assumption 2.1. The optimal design is uniquely characterized in terms of the canonical moments of its factors. The support points and the weights of the $j$th factor $\xi_j$ with canonical moments (13) can be identified by standard methods (see Studden, 1982a) and a corresponding result is given in the Appendix in order to make the paper self-contained.

In the remaining part of this section we consider an alternative optimality criterion which might be useful if the main interest of the experimenter is the parameters corresponding to the “highest” powers in the model. To this end let $s = m - n$ (n < m) and consider a partition of the information matrix

$$M(\eta) = \begin{pmatrix} M_{11}(\eta) & M_{12}(\eta) \\ M_{21}(\eta) & M_{22}(\eta) \end{pmatrix},$$

where $M_{11}(\eta)$ denotes the information matrix of the design $\eta$ in the “incomplete” model of degree $n < m$. A D$_1$-optimal design maximizes

$$|M_{22}(\eta) - M_{21}(\eta)M_{11}(\eta)M_{12}(\eta)| = \frac{|M(\eta)|}{|M_{11}(\eta)|}$$

which is proportional to the determinant of the inverse covariance matrix of the least squares estimator for the $s = m - n$ “highest” coefficients [n < m] corresponding to the multiple

monomials
\[
\sum_{j=1}^{q} x_j^h \quad \text{with} \quad \mathcal{A}_{k_1, \ldots, k_q} = 1 \quad \text{and} \quad \sum_{j=1}^{q} h_j \in \{ n+1, \ldots, m \}
\]
(15)
in the "incomplete" polynomial regression (3). The following result specifies the canonical moments of the $D_s$-optimal product design. Here and throughout this paper we use the definition $\sum_{l=0}^{n} \beta_l = 0$ whenever $l < k$.

**Theorem 2.2**

A $D_s$-optimal product design for the "highest $s = m - n \ (n < m)$ coefficients" specified by (15) in an "incomplete" polynomial regression (3) satisfying assumption 2.1 is given by

\[
\mathbf{\hat{\eta}} = \xi_1 \times \cdots \times \xi_q. \quad \text{Here, for } j = 1, \ldots, q, \text{ the } j\text{th factor } \xi_j \text{ of the } D_s\text{-optimal product design } \mathbf{\hat{\eta}} \text{ has canonical moments}
\]

\[
p_{m-1}^{(l)} = \frac{1}{2}, \quad l = 1, \ldots, m_j,
\]

\[
p_{m}^{(l)} = \frac{\sum_{i=l}^{m} \mathcal{A}(i, j, m) - \sum_{i=l}^{n} \mathcal{A}(i, j, n)}{\sum_{i=l}^{m} \mathcal{A}(i, j, m) - \sum_{i=l}^{n} \mathcal{A}(i, j, n) + \sum_{i=l+1}^{m} \mathcal{A}(i, j, m) - \sum_{i=l+1}^{n} \mathcal{A}(i, j, n)}, \quad l = 1, \ldots, \min \{ n, m_j \},
\]

\[
p_{m}^{(l)} = \frac{\sum_{i=l}^{m} \mathcal{A}(i, j, m)}{\sum_{i=l}^{m} \mathcal{A}(i, j, m) + \sum_{i=l+1}^{m} \mathcal{A}(i, j, m)}, \quad l = \min \{ n, m_j \} + 1, \ldots, m_j,
\]

with the convention that this sequence terminates at $p_{m_0}^{(l)}$ whenever $p_{m_0}^{(l)}$ is 0 or 1 ($1 \leq l_0 \leq m_j$) and 0/0 is defined as 0.

**Proof.** The symmetry (which implies $p_{m-1}^{(l)} = 1/2$) is obtained by standard arguments. By a similar reasoning as in the proof of theorem 2.1 it follows that the $D_s$-optimal product design is given by $\mathbf{\hat{\eta}} = \xi_1 \times \cdots \times \xi_q$ where $\xi_j$ maximizes the factor

\[
B_j(\xi_j) = \prod_{i=1}^{m} \left( \int_{-1}^{1} W^{2}_{i,j}(\xi_j) \, d\xi_j(\xi_j) \right)^{\sigma(i,j,m)} \prod_{l=1}^{m} \left( \int_{-1}^{1} W^{2}_{i,j}(\xi_j) \, d\xi_j(\xi_j) \right)^{\sigma(i,j,n)}.
\]

Expressing $B_j(\xi_j)$ in terms of canonical moments of the measure $\xi_j$ we obtain by straightforward algebra

\[
B_j(\xi_j) = \prod_{l=1}^{m} (q_{m-2}^{(l)} p_{m}^{(l)})^{\sigma(l,j,m) - \sigma(l,j,n)} \prod_{l=n+1}^{m} (q_{m-2}^{(l-1)} p_{m}^{(l)})^{\sigma(l,j,m)} \prod_{l=1}^{m} (q_{m-2}^{(l)} p_{m}^{(l)})^{\sigma(l,j,m)}
\]
(17)

with $\sigma(l,j,m) = \sum_{k=1}^{m} \mathcal{A}(i,j,m)$. If $n < m_j$, it is easy to see that $\sigma(l,j,m) - \sigma(l,j,n) > 0$ ($l = 1, \ldots, n$) and that $\sigma(l,j,m) > 0$ ($l = n+1, \ldots, m_j$). Thus the assertion follows directly by maximizing (17). The remaining case $n \geq m_j$ is more delicate. In this case $B_j(\xi_j)$ reduces to

\[
B_j(\xi_j) = \prod_{l=1}^{m_j} (q_{m-2}^{(l)} p_{m}^{(l)})^{m_j}
\]
(18)
where

\[ n_i = \sigma(l, j, m) - \sigma(i, j, n) = \sum_{i=1}^{m_j} S_{i,j}^m - S_{i,j}^n \]

\[ = \sum_{i=1}^{m_j} \sum_{j=1}^{n_m} h_l \leq m \, S_{i,j} \bigg| h_l \leq m - 1, \ldots, h_m \bigg] \]  \hspace{1cm} (19)

In the last line we used \( S_{i,j} = 0 \) for \( i > m_j \) and \( r \in \{n, m\} \) (which is immediate from the definition of \( m_j \) and (12)). From (19) we have \( n_i \geq n_2 \geq \cdots \geq n_{m_j} \geq 0 \) and defining \( l_0 + 1 = \min \{ l \mid 1 \leq l \leq m_j, n_j = 0 \} \) we obtain from (18)

\[ B_j(\xi_j) = \prod_{l=1}^{l_0} (q_{l,j}^{-1} p_{l,j}^0)^m. \]

If \( l_0 = 0 \), then \( \xi_j \) can be chosen arbitrarily. We put \( p_{l,j}^0 = 0 \) which corresponds to the assertion of the theorem and obtain the factor design \( \xi_j \) with mass 1 at the point 0. If \( l_0 = 1 \) we obtain \( p_{l,j}^0 = 1 \) and \( p_{l,j}^0 = n_j/(n_j + n_{l+1}) \) \((1 \leq l \leq l_0)\) which is (16) in the case \( n \geq m_j \). \( \square \)

**Remark 2.1.** The proof of theorem 2.2 can quite easily be adapted to the designing problem for the estimation of any subset of parameters in the model (3) which complement a submodel of (3) satisfying assumption 2.1. \( \square \)

**Remark 2.2.** Theorems 2.1 and 2.2 consider the design space \([-1, 1]^q\) but the results can easily be transformed to arbitrary cubes of the form \( \prod_{j=1}^{q} [a_j, b_j] \) using a similar argument as in Fedorov (1972, p. 80) and assumption 2.1. The support points of the factors \( \xi_j \) have to be transformed linearly while the masses remain unchanged. The canonical moments of the factors \( \xi_j \) of the optimal product designs are invariant under such a transformation and the reader can identify the optimal product design directly from (13) and (16) using the results of the Appendix. \( \square \)

### 3. Examples

Theorems 2.1 and 2.2 are now illustrated by several examples.

**Example 3.1.** Consider the model (4). By theorem 2.1 and (5) we obtain for the D-optimal product design \( \eta = \xi \times \xi \times \xi \) where \( \xi, \xi \) have canonical moments

\[ p^{(j)} = \frac{1}{2}, \; p^{(j)} = 1 \; \; (j = 2, 3) \]

and the canonical moments of \( \xi \) are

\[ p^{(1)} = p^{(1)} = \frac{1}{2}, \; p^{(1)} = \frac{3}{4}, \; p^{(1)} = 1. \]

The results of theorem A.1 in the Appendix give for the factors of the optimal product design

\[ \xi = \begin{pmatrix} -1 & 0 & 1 \\ \frac{1}{2} & 1 & \frac{1}{2} \end{pmatrix}, \; \xi = \begin{pmatrix} -1 & 0 \\ \frac{1}{2} & 1 \end{pmatrix} \]

If we are interested in the estimation of the parameters corresponding to the terms \( x_1 x_2 \) and \( x_1 \) we apply theorem 2.2 (with \( m = 2, n = 1, m_1 = 2, m_2 = 1, m_3 = 1 \) and obtain for the
canonical moments of the factors of the $D_1$-optimal product design
\[ p_1^{(1)} = p_3^{(1)} = \frac{1}{2}, \quad p_2^{(1)} = \frac{2}{3}, \quad p_4^{(1)} = 1 \]
\[ p_1^{(2)} = \frac{1}{2}, \quad p_2^{(2)} = 1 \]
\[ p_1^{(3)} = \frac{1}{2}, \quad p_2^{(3)} = 0. \]

By theorem A.1 a $D_1$-optimal product design is given by $\hat{\eta} = \xi_1 \times \xi_2 \times \xi_3$, where
\[ \xi_1 = \begin{pmatrix} -1 \\ \frac{1}{3} \\ \frac{1}{3} \\ \frac{1}{3} \end{pmatrix}, \quad \xi_2 = \begin{pmatrix} -1 \\ \frac{1}{2} \\ \frac{1}{2} \\ 1 \end{pmatrix}, \quad \xi_3 = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}. \]

Note that this design has a singular information matrix for estimating all parameters in model (4) because the factor $\xi_3$ puts mass 1 at the point 0. Other $D_1$-optimal product designs can be obtained by using arbitrary symmetric measures for the design $\xi_3$—see the proof of theorem 2.2.

Example 3.2. Consider the model $[m = 3, q = 2]$
\[ x_0 + \alpha_1 x_1 + \alpha_2 x_2 + \alpha_3 x_1^2 + \alpha_4 x_1^3 + \alpha_5 x_1^2 x_2 \]
(20)
on the design space $[-1, 1]^2$. Assumption 2.1 is easily verified using the matrix $Q = I_6$.

\[ A_{\eta} = \begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 \\
-\frac{1}{2} & 0 & 0 & 0 & 0 & 0 \\
0 & -\frac{1}{2} & -\frac{1}{2} & 0 & 0 & 0 \\
0 & 0 & 0 & -\frac{1}{2} & 0 & 0
\end{pmatrix} \]

and the vector of regression functions $f(x) = (1, x_1, x_2, x_1^2, x_1^3, x_1^2 x_2)^T$. For the quantities $J_{h_1, h_2}$ in the model (3) we have
\[ J_{0, 0} = J_{1, 0} = J_{0, 1} = J_{2, 0} = J_{3, 0} = J_{2, 1} = 1 \]
\[ J_{0, 2} = J_{1, 2} = J_{0, 3} = J_{1, 1} = 0 \]

and the $D$-optimal product design is given by $\eta^* = \xi_1^* \times \xi_2^*$ where the canonical moments of $\xi_1^*$ and $\xi_2^*$ are specified in (13). Thus we obtain
\[ p_1^{(1)} = p_3^{(1)} = \frac{1}{2}, \quad p_2^{(1)} = \frac{3}{4}, \quad p_4^{(1)} = \frac{3}{4}, \quad p_6^{(1)} = 1 \]

which gives by theorem A.1 for the first factor of the $D$-optimal product design
\[ \xi_1^* = \begin{pmatrix} -1 \\ \frac{1}{4} \\ \frac{1}{4} \\ \frac{1}{4} \\ \frac{1}{4} \\ \frac{1}{4} \end{pmatrix}. \]

Similarly it follows from $p_1^{(2)} = \frac{1}{2}, p_2^{(2)} = 1$ that the second factor is given by
\[ \xi_2^* = \begin{pmatrix} -1 \\ \frac{1}{2} \\ 1 \\ 0 \\ 0 \end{pmatrix}. \]

In order to calculate the optimal product design for estimating the coefficients of $x_1^2, x_1^3 x_2$ and $x_1^3$ we apply theorem 2.2 and calculate the canonical moments of the factors of the $D_2$-optimal product design $[m = 3, n = 1]$ as
\[ p_1^{(1)} = p_3^{(1)} = \frac{1}{2}, \quad p_2^{(1)} = \frac{1}{2}, \quad p_4^{(1)} = \frac{3}{4}, \quad p_6^{(1)} = 1 \]
\[ p_1^{(2)} = \frac{1}{2}, \quad p_2^{(2)} = 1. \]

By theorem A.1 we obtain the $D_2$-optimal product design for the model (20) as $\hat{\xi} = \xi_1 \times \xi_2$,

$$
\xi_1 = \begin{pmatrix}
-1 \\
3/4 \\
-1/2 \\
3/4
\end{pmatrix},
\xi_2 = \begin{pmatrix}
-1 \\
1/2 \\
1/2
\end{pmatrix}.
$$

Example 3.3. Consider the "complete" model (1), i.e. $J_{h_1, \ldots, h_q} = 1$ for all $h_1, \ldots, h_q \in \{0, \ldots, m\}$ with $\sum_{j=1}^q h_j \leq m$. In this case we have

$$
J(i, j, m) = \sum_{\sum_k h_k \leq m-i} 1 = \binom{m-i+q-1}{q-1}
$$

and obtain by theorems 2.1 and 2.2 the results of Lim & Studden (1988). For example, the even canonical moments of the factors of the $D$-optimal product design are given by

$$
p_{2l}^{(q)} = \frac{\sum_{i=1}^m \binom{m-i+q-1}{q-1} + \sum_{i=l+1}^m \binom{m-i+q-1}{q-1} = \binom{m-l+q-1}{q-1}}{q + 2(m-l)}, \quad l = 1, \ldots, m
$$

independently of $j = 1, \ldots, q$. Here the second line follows from the identity

$$
\sum_{j=0}^{i} \binom{q-1+j}{q-1} = \binom{q+i}{q}
$$

(see Scheffé, 1958, p. 356).

4. Multivariate regression with missing "highest" terms

Consider the "complete" model, where some of the powers $x_j^m$ are not present in the model. Thus we have in model (3)

$$
J_{0, \ldots, 0} = J_{0, m, 0, \ldots, 0} = \cdots = J_{0, \ldots, 0, m, 0, \ldots, 0} = 1
$$

and (3) reduces to

$$
Y(x) = a_0 + \sum_{j=1}^q a_j x_j + \sum_{1 \leq i_1 < i_2 \leq q} a_{i_1, i_2} x_{i_1} x_{i_2} + \cdots
$$

$$
+ \sum_{1 \leq i \leq m} \sum_{1 \leq j \leq l_i \leq q} \alpha_{i, l_i} x_j + \sum_{j=1}^k \beta_j x_j^m.
$$

The quadratic case (i.e. $m = 2$) has been investigated by Uppermann (1993) who found the $D$-optimal designs explicitly using the Kiefer and Wolfowitz equivalence theorem. Even this case requires an extremely tedious analysis (see Uppermann, 1993) and it seems to be intractable to obtain the optimal designs explicitly for polynomials of higher degree. However, the results of section 2 show that the optimal product designs can be described in terms of the canonical moments of their factors. To this end we observe that assumption 2.1
is satisfied and obtain from (22) and example 4.3

\[ \mathcal{J}(i, j, m) = \sum_{\sum_{h_j=1}^{l} n_j \leq m} \mathcal{J}_{h_1, \ldots, h_k} = \binom{m - i + q - 1}{q - 1} \quad j = 1, \ldots, k \]

\[ \mathcal{J}(i, j, m) = \begin{cases} 
\binom{m - i + q - 1}{q - 1} & \text{if } 1 \leq i \leq m - 1 \\
0 & \text{if } i = m \end{cases} \quad j = k + 1, \ldots, m \]

which implies (using the identity (21))

\[ \sum_{i=1}^{m} \mathcal{J}(i, j, m) = \begin{cases} 
\binom{m - l + q}{q} & \text{if } j = 1, \ldots, k \\
\binom{m - l + q}{q} - 1 & \text{if } j = k + 1, \ldots, m 
\end{cases} \]

Now straightforward algebra yields the following result.

**Theorem 4.1**

The D-optimal product design for the model (23) is given by

\[ \eta^* = \frac{\xi_1^* \times \cdots \times \xi_i^* \times \xi_{i+1}^* \times \cdots \times \xi_k^*}{q-k} \]

where the designs \(\xi_1^*\) and \(\xi_k^*\) are uniquely determined by their canonical moments

\[ p_{2l-1}^{(1)} = \frac{1}{2}, \quad p_{2l}^{(1)} = \frac{q + m - l}{q + 2(m - l)} \quad (l = 1, \ldots, m) \quad (p_{2m}^{(1)} = 1) \]

and

\[ p_{2l-1}^{(2)} = \frac{1}{2} \quad (l = 1, \ldots, m - 1) \]

\[ p_{2l}^{(2)} = \frac{(q + m - l)! - (m - l)!q!}{(q + m - l)! + (m - l)(q + m - l - 1)! - 2(m - l)!q!} \quad (l = 1, \ldots, m - 2) \]

\[ p_{2m-2}^{(2)} = 1 \]

The \(D_{\gamma}\)-optimal design can be calculated in a similar way. As an example we consider the case \(n = m - 1\), which is of particular interest for testing if the degree of the multivariate polynomial (23) is \(m\) or \(m - 1\). The proof of the following result is omitted for the sake of brevity.

**Theorem 4.2**

The \(D_{\gamma}\)-optimal product design for the "incomplete" multivariate polynomial regression model (23) is given by

\[ \hat{\eta} = \frac{\hat{\xi}_1 \times \cdots \times \hat{\xi}_i \times \hat{\xi}_{i+1} \times \cdots \times \hat{\xi}_k}{q-k} \]

where the designs \(\hat{\xi}_1\) and \(\hat{\xi}_k\) are uniquely determined by their canonical moments

\[ p_{2l-1}^{(1)} = \frac{1}{2}, \quad p_{2l}^{(1)} = \frac{q - 1 + m - l}{q + 2(m - l)} \quad (l = 1, \ldots, m) \quad (p_{2m}^{(1)} = 1) \]
and

\[ p^{(2)}_{m-1} = \frac{1}{2} \quad (l = 1, \ldots, m - 1) \]

\[ p^{(2)}_l = \frac{m - l + q - 1 - (q - 1)!}{2(m - l) + q - 1 - 2(q - 1)!} \frac{(m - l)!}{(m - l - 2 + q)!} \quad (l = 1, \ldots, m - 2) \]

\[ p^{(2)}_{m-2} = 1, \]

respectively.

**Example 4.1.** Let \( m = 3, q = 2, k = 1 \) and consider the model (23) on the square \([-1, 1]^2\), which gives

\[ Y(x) = \alpha_0 + \alpha_1 x_1 + \alpha_2 x_2 + \alpha_3 x_1^2 + \alpha_4 x_1^2 + \alpha_5 x_1 x_2 + \alpha_6 x_1 x_2^2 + \alpha_7 x_1^2 x_2 + \alpha_8 x_1^3 \]

(compared to the complete model (1) only the term \( x_3^2 \) is missing). Theorem 4.1 yields for the D-optimal product design \( \eta^* = \xi_1^* \times \xi_2^* \) where the canonical moments of \( \xi_1^* \) and \( \xi_2^* \) are given by

\[ p^{(1)}_{1} = p^{(1)}_{2} = p^{(1)}_{3} = \frac{1}{2}, \quad p^{(1)}_{1} = \frac{1}{2}, \quad p^{(1)}_{2} = \frac{3}{4}, \quad p^{(1)}_{3} = 1 \]

\[ p^{(2)}_{1} = p^{(2)}_{2} = \frac{1}{2}, \quad p^{(2)}_{1} = \frac{3}{4}, \quad p^{(2)}_{2} = 1, \]

respectively. Now theorem A.1 in the Appendix gives for the support points and weights of the designs \( \xi_1^* \) and \( \xi_2^* \)

\[ \xi_1^* = \left( \begin{array}{c} -1 \\ \frac{-1}{10} \\ \frac{-1}{3} \\ \frac{-1}{10} \\ 1 \end{array} \right) \quad \xi_2^* = \left( \begin{array}{c} -1 \\ 0 \\ 1 \end{array} \right) \]

and \( \eta^* = \xi_1^* \times \xi_2^* \) is the D-optimal product design. Similarly, it can be shown that the D1-optimal product design (i.e. the design for estimating the coefficients \( x_1, x_2, x_1^2, x_2^2 \)) is given by \( \hat{\eta} = \xi_1^* \times \xi_2^* \) where

\[ \xi_1 = \left( \begin{array}{c} -1 \\ \frac{-1}{4} \\ \frac{-1}{4} \\ \frac{-1}{4} \\ 1 \end{array} \right) \quad \xi_2^* = \left( \begin{array}{c} -1 \\ 0 \\ 1 \end{array} \right) \]

Note that \( \xi_1 \) and \( \xi_2^* \) are the D-optimal designs for a cubic and quadratic univariate polynomial regression (see Atkinson & Donev, 1992, p. 125).

**Corollary 4.1**

The D1-optimal product design for the bivariate polynomial regression (23) with \( q = 2, m \in \mathbb{N} \) and \( k = 1 \) is given by \( \hat{\eta} = \xi_1^* \times \xi_2^* \) where \( \xi_1 \) and \( \xi_2^* \) are the D-optimal designs for a univariate polynomial regression of degree \( m \) and \( m - 1 \), respectively.

**Proof.** By theorem 4.2 the even canonical moments of \( \xi_1 \) and \( \xi_2^* \) are

\[ p^{(1)}_{2l} = \frac{m - l + 1}{2(m - l) + 1} \quad l = 1, \ldots, m \]

and

\[ p^{(2)}_{2l} = \frac{m - l - 1}{2(m - l) - 1} = \frac{m - l + 1}{2(m - l - 1) + 1} \quad l = 1, \ldots, m - 1 \]
Table 1. D-efficiencies of the D-optimal product designs \( \eta^* \) for the “incomplete” quadratic model (23) with \( q - k \) missing terms. \( \mu^* \) denotes the D-optimal design

| \(| \) | \(| k \) | \(| h_{k,q,m} \) | \( \text{det M}_2(\eta^*_p) \) | \( \text{det M}_2(\eta^*) \) | D-efficiencies |
|---|---|---|---|---|---|
| 1 | 1 | 3 | 0.148148 | 0.148148 | 1 |
| 2 | 1 | 5 | 0.105469 | 0.105469 | 1 |
|  | 2 | 6 | 0.1112 \times 10^{-1} | 0.1143 \times 10^{-1} | 0.99553 |
| 3 | 1 | 8 | 0.8192 \times 10^{-1} | 0.8192 \times 10^{-1} | 1 |
|  | 2 | 9 | 0.6711 \times 10^{-2} | 0.6815 \times 10^{-2} | 0.99830 |
|  | 3 | 10 | 0.5498 \times 10^{-3} | 0.5783 \times 10^{-3} | 0.99495 |
| 4 | 1 | 12 | 0.6698 \times 10^{-1} | 0.6698 \times 10^{-1} | 1 |
|  | 2 | 13 | 0.4486 \times 10^{-2} | 0.4531 \times 10^{-2} | 0.99924 |
|  | 3 | 14 | 0.3005 \times 10^{-3} | 0.3102 \times 10^{-3} | 0.99772 |
|  | 4 | 15 | 0.2013 \times 10^{-4} | 0.2157 \times 10^{-4} | 0.99539 |
| 5 | 1 | 17 | 0.5665 \times 10^{-1} | 0.5565 \times 10^{-1} | 1 |
|  | 2 | 18 | 0.3210 \times 10^{-2} | 0.3232 \times 10^{-2} | 0.99962 |
|  | 3 | 19 | 0.1818 \times 10^{-3} | 0.1859 \times 10^{-3} | 0.99885 |
|  | 4 | 20 | 0.1030 \times 10^{-4} | 0.1080 \times 10^{-4} | 0.99766 |
|  | 5 | 21 | 0.5840 \times 10^{-6} | 0.6348 \times 10^{-6} | 0.99604 |

\((p^{(1)}_{2m} = p^{(2)}_{5m-1} = 1)\). But these are exactly the canonical moments of the D-optimal designs for a (univariate) polynomial regression of degree \( m \) and \( m - 1 \) (see Studden, 1980, which proves the assertion.

It might be of interest to compare the D-optimal product designs of theorem 4.1 with the D-optimal designs calculated by Uppermann (1993) in the quadratic case. To this end we use the D-efficiency

\[
\text{eff} (\eta^*) = \left( \frac{\text{det M}(\eta^*)}{\sup_q (\text{det M}(\eta))} \right)^{\frac{1}{h_{k,q,m}}}
\]

where \( \eta^* \) is the D-optimal product design, the \( \sup \) is taken over all designs on the \( q \)-cube \([-1, 1]^q\) and \( h_{k,q,m} \) is the number of parameters in the model (23) (depending on \( k \), \( q \) and \( m \)). The efficiencies for various values of the parameters \( q \) and \( k \) are listed in Table 1. The results indicate that the D-optimal product designs are highly efficient in all considered cases. It is remarkable that in the case \( k = 1 \) the product designs are also globally D-optimal and that the efficiencies of the product designs are slightly decreasing when \( h_{k,q,m} \) is increasing.

Acknowledgements

The authors are grateful to three unknown referees for their constructive comments on an earlier version of this paper. We are also indebted to Professor D. Rasch for drawing our attention to the problem of optimal design in “incomplete” multivariate regression models. Parts of the paper were written while the first author was visiting the University of Göttingen and this author would like to thank the Institut für Mathematische Stochastik for its hospitality.

**Appendix**

The following result provides an efficient tool for calculating the support points and weights of a design corresponding to a terminating sequence of canonical moments (see Röder, 1994 for a detailed proof).

**Theorem A.1**

Let \( \xi \) denote a probability measure in the interval \([a, b]\), \(a, b \in \mathbb{R} \ (a < b)\) with canonical moments \( p_j \in (0, 1) \) for \( j = 1, \ldots, 2m - 1 \) and \( p_{2m} = 1 \), define \( \zeta_1 = p_1, \gamma_1 = q_1, \zeta_j = q_{j-1}p_j, \gamma_j = q_{j-1}q_j \) (\( j = 2, \ldots, m \)).

\( \xi \) has exactly \( m + 1 \) support points \( a = x_0 < x_1 < \cdots < x_{m-1} < x_m = b \), which are the roots of the polynomial

\[
\tilde{Q}_{m+1}(x) := (x-a)(x-b)Q_{m-1}(x).
\]

The weights at these points are:

\[
\xi(x_j) = \frac{\frac{d}{dx} \tilde{Q}_{m+1}(x)|_{x=x_j}}{P_m(x_j)} \quad j = 0, \ldots, m
\]

Here the polynomials \( P_j(x) \), \( Q_j(x) \) are defined recursively by \( Q_{-1}(x) = P_{-1}(x) = 0, \).
\[ Q_0(x) = P_0(x) = 1 \]

\[ Q_{j+1}(x) = \left[ x - a - (b - a)(\gamma_{2j+2} + \gamma_{2j+3}) \right] Q_j(x) - (b - a)^2 \gamma_{2j+1} \gamma_{2j+2} Q_{j-1}(x) \]

\[ (0 \leq j \leq m - 2) \]

\[ P_{j+1}(x) = \left[ x - a - (b - a)(\xi_{2j+2} + \xi_{2j+3}) \right] P_j(x) - (b - a)^2 \xi_{2j+1} \xi_{2j+2} P_{j-1}(x) \]

\[ (0 \leq j \leq m - 2), \]

and

\[ P_m(x) = \left[ x - a - (b - a)\xi_{2m} \right] P_{m-1}(x) - (b - a)^2 \xi_{2m-1} \xi_{2m} P_{m-2}(x). \]
